## Interventions in clinical acute renal failure: what are the data?

Conger

JD.

Division of Renal Diseases and Hypertension, University of Colorado Health Sciences Center, Denver, USA.

A variety of therapeutic approaches have been used both to prevent acute ischemic and nephrotoxic renal injury and to improve renal function and reduce mortality once acute renal failure (ARF) has developed. Unfortunately, there have been few rigorous assessments of the efficacy of these treatment interventions. The reasons for the lack of abundant critical data regarding treatment effects in ARF are several. First, ARF is a functional disorder. It has a spectrum of etiologies, occurs in a variety of clinical settings and varies in severity. Second, selected endpoints of treatment success vary and co-morbid factors frequently

## TRATAMIENTO

Prophylaxis of acute renal failure in patients with rhabdomyolysis.

Homsi E, Barreiro MF, Orlando JM, Higa EM. Ren Fail 1997;19: 283-288

Intensive Care Unit, Hospital Municipal Artur Ribeiro de Saboya, São Paulo, Brazil.

Patients that develop rhabdomyolysis of different causes are at high risk of acute renal failure. Efforts to minimize this risk include volume repletion, treatment with mannitol, and urinary alkalinization as soon as possible after muscle injury. This is a retrospective analysis (from January 1, 1992, to December 31, 1995) of therapeutic response to prophylactic treatment in patients with rhabdomyolysis admitted to an intensive care unit (ICU). The diagnosis of rhabdomyolysis was based on creatinine kinase (CK) level ( $> 500$  U/L) and the criteria for prophylaxis were: time elapsed between muscle injury to ICU admission  $< 48$  h and serum creatinine  $< 3$  mg/dL. Fifteen patients were treated with the association of saline, mannitol, and sodium bicarbonate (S + M + B).

Demetrios Demetriades, MD, PhD, and George C. Velmahos, MD, PhD*

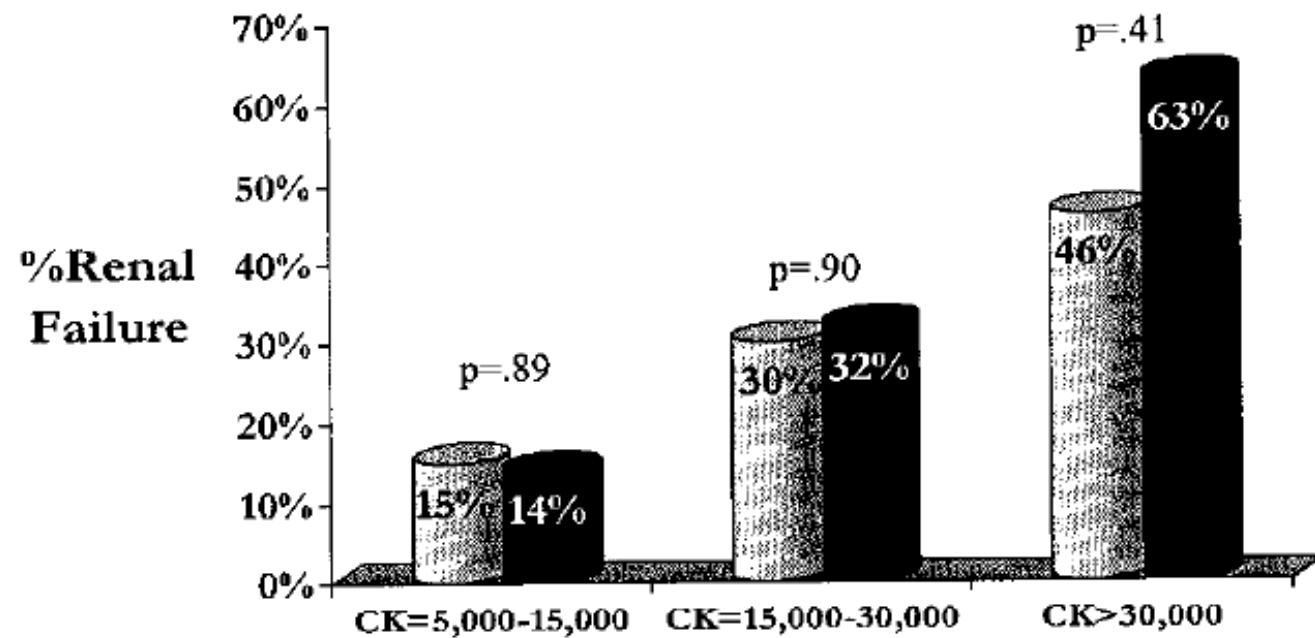

*J Trauma.* 2004;56:1191–1196.

**Conclusion:** Abnormal CK levels are common among critically injured patients, and a CK level greater than 5,000

U/L is associated with RF. BIC/MAN does not prevent RF, dialysis, or mortality in patients with creatine kinase levels greater than 5,000 U/L. The standard of administering BIC/MAN to patients with post-traumatic rhabdomyolysis should be re-evaluated.

### Extracorporeal therapies in acute rhabdomyolysis and myoglobin clearance

Claudio Ronco

(55)

#### Abstract

Rhabdomyolysis is a pathogenetic cause of acute kidney injury. In such circumstances, not only should therapeutic strategies to replace the failing kidney be implemented, but measures should also be explored to prevent further damage by circulating myoglobin. Volume expansion and forced diuresis have been used, but when a kidney fails, renal replacement therapies are instituted.

The techniques and devices used for classic dialytic techniques have displayed a limited capacity for the removal of circulating myoglobin. In a recent paper, Naka and colleagues have proposed the use of a super-high-flux membrane in continuous hemofiltration. The removal of myoglobin was greater than in than any previous report. Thus, if the removal of myoglobin is desirable, a combination of continuous hemofiltration and hyperpermeable membranes seems to be the most effective. However, care must be exercised to prevent unwanted albumin losses.
